DATE October 30, 1973

SUBJECT PILE LOAD TEST
BRIDGE NO. 12
PIN 9357.02

FROM Robert C. Houghton, Senior Soils Engineer RCH

TO Bernard E. Butler, Associate Soils Engineer ✓

The attached Pile Load Test Report represents the summary of all activities which were initiated for the design, testing and installation of piles for this structure.

The pile load test was the second one which New York State has performed under Specification 88 PLT. The cost of the load test is $15,000.

This report prepared by Robert McCarty and Robert Houghton represents the first attempt at a comprehensive review and analysis of the pile load test data. It is planned to prepare a similar report for all future pile load tests which are progressed.

LIST OF FIGURES

INTRODUCTION

1. On July 16 through July 18 and July 23, 1973 a Pile Load Test, in accordance with Item 88 PLT as described in the proposal, was performed at the site of the West Abutment of the Eastbound Bridge of Bridge #12, Mainline over the Susquehanna River of I-88, Susquehanna Expressway (PIN 9357.02 311, FISH 72-5). The Pile Load Test was performed on an HP 12 x 53, 26 feet in length with approximately 25 feet in the ground. Two telltales were provided for the purpose of determining the amount of resistance carried by the tip and by the side of the pile. An H-pile is not usually used as a friction pile, but the soil type encountered at this site would not readily permit the driving of displacement type piles, which are commonly used as friction piles.

   This load test consisted of a static load test and two constant rate of penetration (CRP) tests. The purpose of the second CRP is discussed in Appendix A of the report.

   Those present during the field testing were as follows:

Ernest Mosley Ronald Heller Mario Goldberg	-	Raamot Associates (Contractor's Engineering Consultant for P.L.T.)
Philip Smith Gary Beckley Kenneth Freebern	-	Guild Moulton (Bridge Subcontractor)
Philip Pollard	-	NYS DOT E.I.C.
Brian Williams	-	NYS DOT Inspector
Ronald Sickles	-	" " "
John Cobb	-	" " "
Robert Houghton	-	NYS DOT Soil Mechanics Bur.
Robert McCarty	-	NYS DOT Soil Mechanics Bur.

   Most of the details of the pile load test setup, pile, pile driver and associated equipment can be found in Pile Load Test Report (Appendix A) submitted by the Contractor which is attached to this report. Pictures of the test set-up are also included with the Test Report.

Basic Load Test Equipment Used

   The pile load test was conducted by jacking against the dead weight of approximately 200 tons of H-piles. Timber cribbing was placed beneath the H-piles to provide sufficient working

room. A reference beam, located on the north side of the test pile running in an east-west direction was supported on two 6 inch diameter steel pipes driven into the subsoil a depth of ten feet. The west end of the reference beam was fixed to the steel pipe by weld while the east end of the beam was permitted to move. The reference beam projections completely surrounded the test pile, with 5 dial gages clamped to it. Two gages were for the telltale movement; the northerly one for the pile movement in the alluvial material, and the southerly one for the movement of the tip of the pile. The remaining three dial gages were placed on the outside of the flange, one on the west side of the pile and two on the east side. A back-up measuring system consisting of a wire and mirror was also used. A load cell containing approximately 30 SR-4 strain gages was used to determine the load on the pile. This system was used in conjunction with the pressure gage connected to the jack's fluid line.

2. Subsurface Conditions

The subsurface soils at the site consist of 2 to 3 feet of fill material over 13 feet of very loose brown silt with some sand and a trace of clay over 60 feet of medium compact to very compact brown gravel with some sand and silt and a trace of clay containing boulders, over bedrock. The very loose material is recent alluvium underlain by glacial outwash.

The subsurface exploration location plan and Generalized Subsurface Profiles may be found on Drawing No. 9SM 1749A and 9SM 1749B R-1 in Appendix B of this report.

3. Design Assumptions

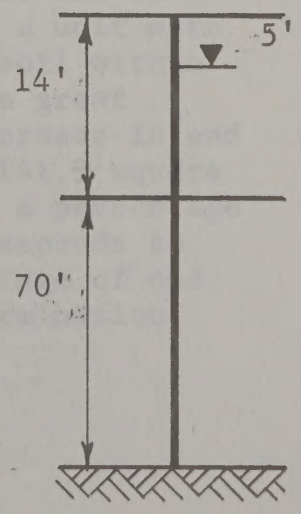
Soil Parameters used in design are as follows.

Very loose brown silt with some sand and a trace of clay

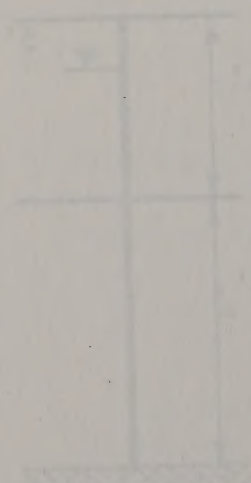
Scourable Material (ϕ &C =o assumed)

Medium compact to very compact brown gravel with some sand and silt and a trace of clay, containing boulders

ϕ = 37.5 C=0



Ledge rock



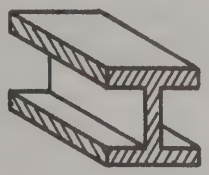
The surface fill material and the alluvial material described as "very loose brown silt with some sand and a trace of clay" were considered to have a high scour potential for design purposes resulting in no contribution to skin friction. In design it was determined that the influence of the surface fill material and alluvial material combined resulted in only 3.5 tons of skin friction for the test pile.

Static Analysis

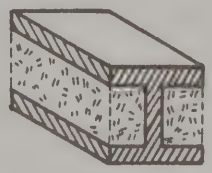
Depending upon the type of soil encountered the failure surface for the tip of an H pile may theoretically be;

a) the actual cross-sectional area of steel,
b) the end area bounded by the least perimeter of the pile tip and soil.

Through the use of telltales on the H-pile tested, the percentage of load carried by the sides of the pile and thence the failure criteria of the soil within the flanges of the pile was determined.



x-section of failure surface at pile tip when soil within flanges does not act as a unit with the H-pile.
End area = 15.58 square inches



x-section of failure surface at pile tip; H-pile and soil within flanges act as a unit during failure.
End area = 141.90 square inches

Static analysis of the two failure types on a 12 x 53 H-pile indicated an ultimate pile capacity of 46 tons for the case where the soil within the flanges did not act as a unit with the H-pile, and 280 tons for the case where the soil within the flanges did act as a unit with the pile. The great disparity in results may be attributed to the increase in end area of the H-piles from 15.58 square inches to 141.9 square inches for the pile and soil unit. Expressed as a percentage of the load carried in end bearing, 46 tons corresponds to 50% and 280 tons corresponds to 90%. The percentage of end bearing is probably the most critical input determination in the wave equation analysis.

Preliminary Wave Equation Analysis

Two wave equation analyses were performed during design with end bearing components of 50% and 90% of the supporting capacity of the pile. The reason for the large difference in percentage of end bearing is discussed in the "Static Analysis" above. The analyses indicated that driving resistances of 2.5 blows per inch for the 50% end bearing and 1.2 blows per inch for the 90% end bearing would be necessary to attain the required ultimate load of 94 tons per pile.

Selected Lengths

The static analysis for total mobilization of steel and soil at the end of the pile and between the flanges resulted in a design length of 17.5 feet. The static analysis for point resistance of only the steel area indicated that a pile length of 35 feet would be required to support an ultimate load of 94 tons. Since more than ten feet of scourable material is present a minimum penetration of 10 feet would be required into firm material. This fact, coupled with an average of the static analyses, resulted in a length of 25 ft. selected for the pile load test.

4. RESULTS AND INTERPRETATION

The pile failed at an ultimate load of approximately 194 tons (Fig. 1) resulting in a safety factor of 4.1. It was, therefore, important to determine the pile length required and driving criteria to be used to insure that the remaining piles were installed efficiently and economically.

Several methods are available for designing pile lengths for a particular structure. The one most frequently used by the Soil Mechanics Bureau is Nordlunds'[1] static analysis. This method is based on the assumed soil strength parameters and yields the ultimate pile capacity. From this method one can also obtain the percentage of pile tip resistance.

The prediction of driving resistance is best determined through use of the wave equation theory based on a pre-determined length of pile necessary to support the known design load. One of the most important elements of input for the wave equation program [2]

is the percent tip resistance. If no pile load test data is available the percentage tip resistance would have to be estimated from the static analysis. Further refinement of input for the wave equation analysis is available through information derived from the pile load test, and even better information is obtained if the pile load test incorporates a telltale. In the absence of a telltale on the test pile VanWeele's method[3] may provide an estimate of the percent tip resistance although it is empirical in nature. However, if the pile has a telltale an exact method for determining the percent tip resistance is available since we know the exact elastic shortening of the pile at any desired load. Chellis[4] gives the following formula for calculating the load, R, which is left in the pile for any specific elastic shortening.

$$R = \frac{\delta AE}{L}$$

The initial static analysis (Nordlund's) for this pile load test indicated that 40% of the load would be supported at the tip. By using VanWeele's method after the test was completed the tip resistance was calculated at approximately 90 percent (Fig. 2). The Chellis method indicates that the percent tip resistance at 2 times the design load is about 70 percent. Plotting up the above percentages versus loads results in graphs as shown in Figure 3. Figure 4 shows the early loading portion of the same curves. It can be seen that the driving resistance increases substantially as the percent tip resistance decreases. Based on these wave equation analyses the blow count which we recommended to the Bridge Subdivision for each of the production piles was 20 blows per ft. (1.7 blows per inch) with a minimum length of 25 feet.

5. RECOMMENDATIONS AND DISCUSSION

Since this was one of the first pile load tests conducted under the new specification, several modifications may be in order. Below are listed some of the items that should be clarified or amended in the new specification.

A. The detail for the telltale attachment was unclear even though it apparently conformed with AISC nomenclature. The telltale pipe became dislodged during the driving of the H-pile because the pipe was inadequately welded to the pile as a result of the misinterpretation. It is recommended that the drawing which shows the welded telltale pipe be modified to make the exact locations of the weld more clear.

B. This specification was not clear as to the exact procedure for removing the loads during the rebound portion of the CRP test. This could be clarified in the new specification by adding the following:

> "After completion of the above procedure, the load shall be removed in increments of 25 percent of the final load achieved. The rebound loads shall be maintained for 1 minute and readings of all dial gages shall be taken and recorded immediately prior to removing the next load increment."

C. As noted in Appendix A of the above report the first CRP test was rejected because of unexplained movement in the reference beam system. It is recommended that the importance of the reference beam installation be emphasized more in the specification so that in future pile load tests this situation will not occur.

D. Based on the limited experience which we have had with pile load tests it appears that the static load portion of the test is not required in all instances. Most of the information desired from the load test is obtained from the CRP. In cases where it is important to know the settlement characteristics during the 24 hour hold portion it would be advisable to conduct the static portion of the test. However, we feel that whether the static test is included or not should be decided on an individual job basis by the Design Engineer.

E. The loading rate for the pile was .01 inches per minute. Consideration based on more study should be given to whether this may be increased to .02 inches per minute, even for short piles.

F. Richard Dudgeon Inc. (Brooklyn, NY) provided a load pacer for application of the load during the CRP. Participants in the load test were very impressed with this unit and it is suggested that it be given serious consideration for

future load tests. The load application through this unit was uniformly and easily applied and adjusted by the operator. It seems to have many advantages over the old system of applying the load manually with a jack.

G. Also used on this test was a load cell device with SR4 strain gages which gave the exact load on the pile. By using the load cell it was easier to determine the load in the pile than by reading the more inaccurate pressure gage on the jack. While not all companies have load cells it is recommended that serious consideration be given for their use on future tests. Since we will be conducting more load tests in the future, it might be feasible for New York State to purchase a load cell of its own.

TABLE OF CONTENTS (continued)

ABSTRACT

The HP12x53 steel test pile, which had been driven vertically to a penetration of 25 feet below grade, was load-tested statically in axial compression to twice its design load of 47 tons which resulted in a gross settlement of 0.15 inches and a net settlement of 0.02 inches. It was subsequently load-tested by the constant rate of penetration method at a rate of 0.01 in/min. to 188 tons which caused progressive failure. Five days later it was again subjected to a similar CRP test to approximately 194 tons which caused progressive failure.

INTRODUCTION

This report presents the results of testing Pile No. 164 in axial compression. This pile is an HP12x53 steel beam, having a design load of 47 tons, which was driven vertically 25 feet below grade at Elevation 955.3 feet. It is located in the east-bound lane of the west abutment to a new bridge over the Susquehanna River near Harpursville, New York.

This pile was tested in accordance with the State of New York specification for this project. This required that the pile be subjected to a static load test in compression to twice its design load, and subsequently be subjected to a constant rate of penetration test to four times its design load, or failure if that occurred first.

In addition to test results, a brief description is given of the soil conditions, how the pile was driven and how it was tested.

SOIL CONDITIONS

The appendix to this report includes a copy of the log for Hole No. DH-39 which is understood to be the nearest soil boring to the test pile. It is understood that the test pile, Pile No. 164, is located at Station 786+00, offset 58.5 feet to the right, according to the base line used for the soil boring locations. Since Hole No. DH-39 is located at Station 785+50, offset 33 feet to the right, the distance from the test pile to the soil boring is approximately 56 feet.

The boring log shows the ground surface elevation to be 954.4 and the driving log for the test pile indicates grade was 955.3. The test pile area is understood to have about 2 feet of fill on the original ground surface which was probably stripped of topsoil before the fill was placed.

The boring log shows the pile penetrated 5 feet of non-plastic silt, 10 feet of very loose fine sand and 10 feet of medium to dense fine to coarse sand and gravel with some silt. The soil below the pile tip to a depth of 41.5 feet where the boring was terminated is shown to be generally coarse sand and gravel with some silt, of medium to dense consistency, increasing in density with depth.

TEST PILE INSTALLATION

The original pile designated for testing is 18.5 feet south of Pile No. 164 which was ultimately tested. The original pile was driven but one of the tell-tale boxes broke loose from the pile during driving so Pile No. 164 was driven after strengthening the connection of the tell-tale boxes to the pile.

The pile was driven with a Link Belt 520 diesel hammer operating at an energy of 22,000 ft-lbs per blow. It was stopped at a penetration of 25 feet below grade where it had a final resistance of 5 blows per inch.

The appendix shows details of the tell-tales and the boxes supporting and protecting them. The pile tip fastened to the HP12x53 beam is also shown. For Pile No. 164, one tell-tale rests 20 inches above the pile tip and the other rests 9 feet above the first one. The tell-tale resting 20 inches above the pile tip is a 1-inch diameter reinforcing bar, and the other is a 2-inch diameter pipe.

A 1-inch thick steel plate was welded to the pile head for supporting the test jack.

LOAD TEST SET-UP

The test load was applied to the pile by means of a hydraulic jack having a 250-ton capacity. For a reaction to the test load, HP12x53 beams having a total weight in excess of 200 tons were stacked over a test beam and supported by two timber cribs. In between the test jack and the test beam a load cell was placed to provide a check system for measuring the test load applied to the pile.

Settlement of the pile butt was measured by three extensometers fastened to a reference beam as shown in the sketches in the appendix. Tell-tale settlements were measured in a similar manner. A wire-mirror-scale system was used as a secondary method of measuring pile butt settlement. A surveyor's level was used to observe any movement the reference beam might experience during the testing. The reference beam was supported by steel pipes driven 10 feet below grade at a distance 10 feet from the test pile. The cribbing supporting the steel beams was more than 10 feet from the test pile. The benchmark used for the surveyor's level was a spike driven into a large tree approximately 75 feet from the test pile.

LOAD-TESTING

The static load test to twice the design load of 47 tons was applied in cycles. It was raised to 47 tons, then reduced to zero, then increased to 94 tons, then reduced to zero again, then increased to 94 tons again and held for 24 hours, then reduced to zero again. The field data sheets and Fig. 1, included in the appendix, show how the load and pile settlement varied with time. Fig. 2 shows a graph of load versus settlement for the static testing. The results were a gross settlement of 0.15 inches and a net settlement of 0.02 inches according to the extensometers.

The first CRP test which consisted of jacking the pile down at a rate of 0.01 inches per minute resulted in a maximum load of 188 tons which produced progressive settlement with no increase in load. The test load was applied by means of a Dudgeon variable speed power pump which facilitated making the pile penetrate at a constant rate.

During this testing it was found the surveyor's level indicated an apparent movement of the reference beam and cribs which varied up to 7/8 inches. A study of the data indicated the apparent movement was erratic and did not reflect cycling of the test load as it would logically do if it were moving. It therefore appeared this data was bad. A check on level readings was made July 20, 1973

using a second surveyor's level. Initial readings on the reference beam and cribbing were made before applying load to the pile, and then after adding increments of load up to 142 tons. Keeping the levels level when making readings was a problem, and required several readjustments per reading. However, after following this procedure, the resulting apparent movements of the cribs and reference beam were very small and followed a logical pattern with respect to the test loading.

It was decided another CRP test should be made using two surveyor's levels with frequent readings. This was done July 23, 1973 with reasonable results. A plot of the apparent vertical movement at each end of the reference beam for each level is shown in the appendix. The calculated apparent movement of the midpoint of the reference beam is within the limits stated in the specifications. Limits in accuracy of the surveyor's level system is believed to account for most of the apparent movement of the reference beam.

During the second CRP test, approximately 194 tons were required to cause the pile to penetrate at a rate of 0.01 inches per minute with no increase in load.

During the static load test there was apparently a problem with the wire-mirror-scale system. On sheet 6 of the field data it can be seen that, between the readings

at 0704 and 1304 July 17th, the scale reading changed 3/64" (0.047") while the three extensometers on the pile butt showed virtually no movement. After this the mirror was reset, but the system continued to show changing readings of 4/64" (0.063") from 1304 to 2304 July 17th while the three extensometers changed only 0.003 inches. This relative movement accounts for the difference in final readings between the two systems after all the load was removed. Although the reason for the problem with the wire-mirror-scale system is not clearly understood, it is recommended that for future tests the wire be suspended over a pully at one end with a weight on it to maintain a constant tension in the wire.

River level readings during testing varied less than one foot. Since the test pile is located near the river bank and the soil is granular, it is reasonable to conclude the ground water at the test pile would lie close to the level of the river. River level readings are recorded in the appendix.

RE: FISH 72-5, FARC 72-151
Data For Load Test Item 88 PLT

Gentlemen:

Please review and submit for approval the following information as required by the specifications under Item 88 PLT:

a) 1. Hammer - Linkbelt Model 520 diesel pile hammer, specifications enclosed.
2. Drive Cap - Linkbelt Model HP-1 Filler; weight, 300 lbs.
3. Cushion and Cap Block - 5 Micarta and 4 aluminum discs, alternately spaced; dimensions, 12"x4¼" high.
4. Rated Hammer Energy - Equivalent W.H. Energy Rating; 26,300 ft.lbs. max.
5. Rate of Operation - 80 to 84 blows per minute under resistance conditions.
6. Height of Fall - Equivalent "WH" ram stroke 62.19 inches.
7. Weight of Ram - 5070 lbs.

b) 1. Pile - 12" BP-53. Weight per LF, 53 lbs; area of steel 15.58 square inches.
2. Point - BP 75750. Distributor, Assoc. Pile & Fitting Corp; dimensions as noted on enclosed print; weight, 28 lbs.

c) 1. Dead Load Type - Load consisting of 200 tons of steel beams.
2. Reaction Beam - Dimensions: 21' long, 14¼"x1½" flange, 30 3/8" x 13/16" web.
3. Load Cell - Capacity, 500 tons; Type, SR-4 Strain Indicator.
4. Test Jacks - Capacity, 250 tons: Richard Dudgeon with nitrogen-operated load control.
5. Reference Beams - 8" BP 36 supported by 2½" pipe driven in ground with beam fixed on one end and free on the opposite end to allow for expansion and contraction.

Sketches and specifications on equipment are enclosed.

Very truly yours,

Phil Smith
New York District Manager
Guild-Moulton Const. Corp.

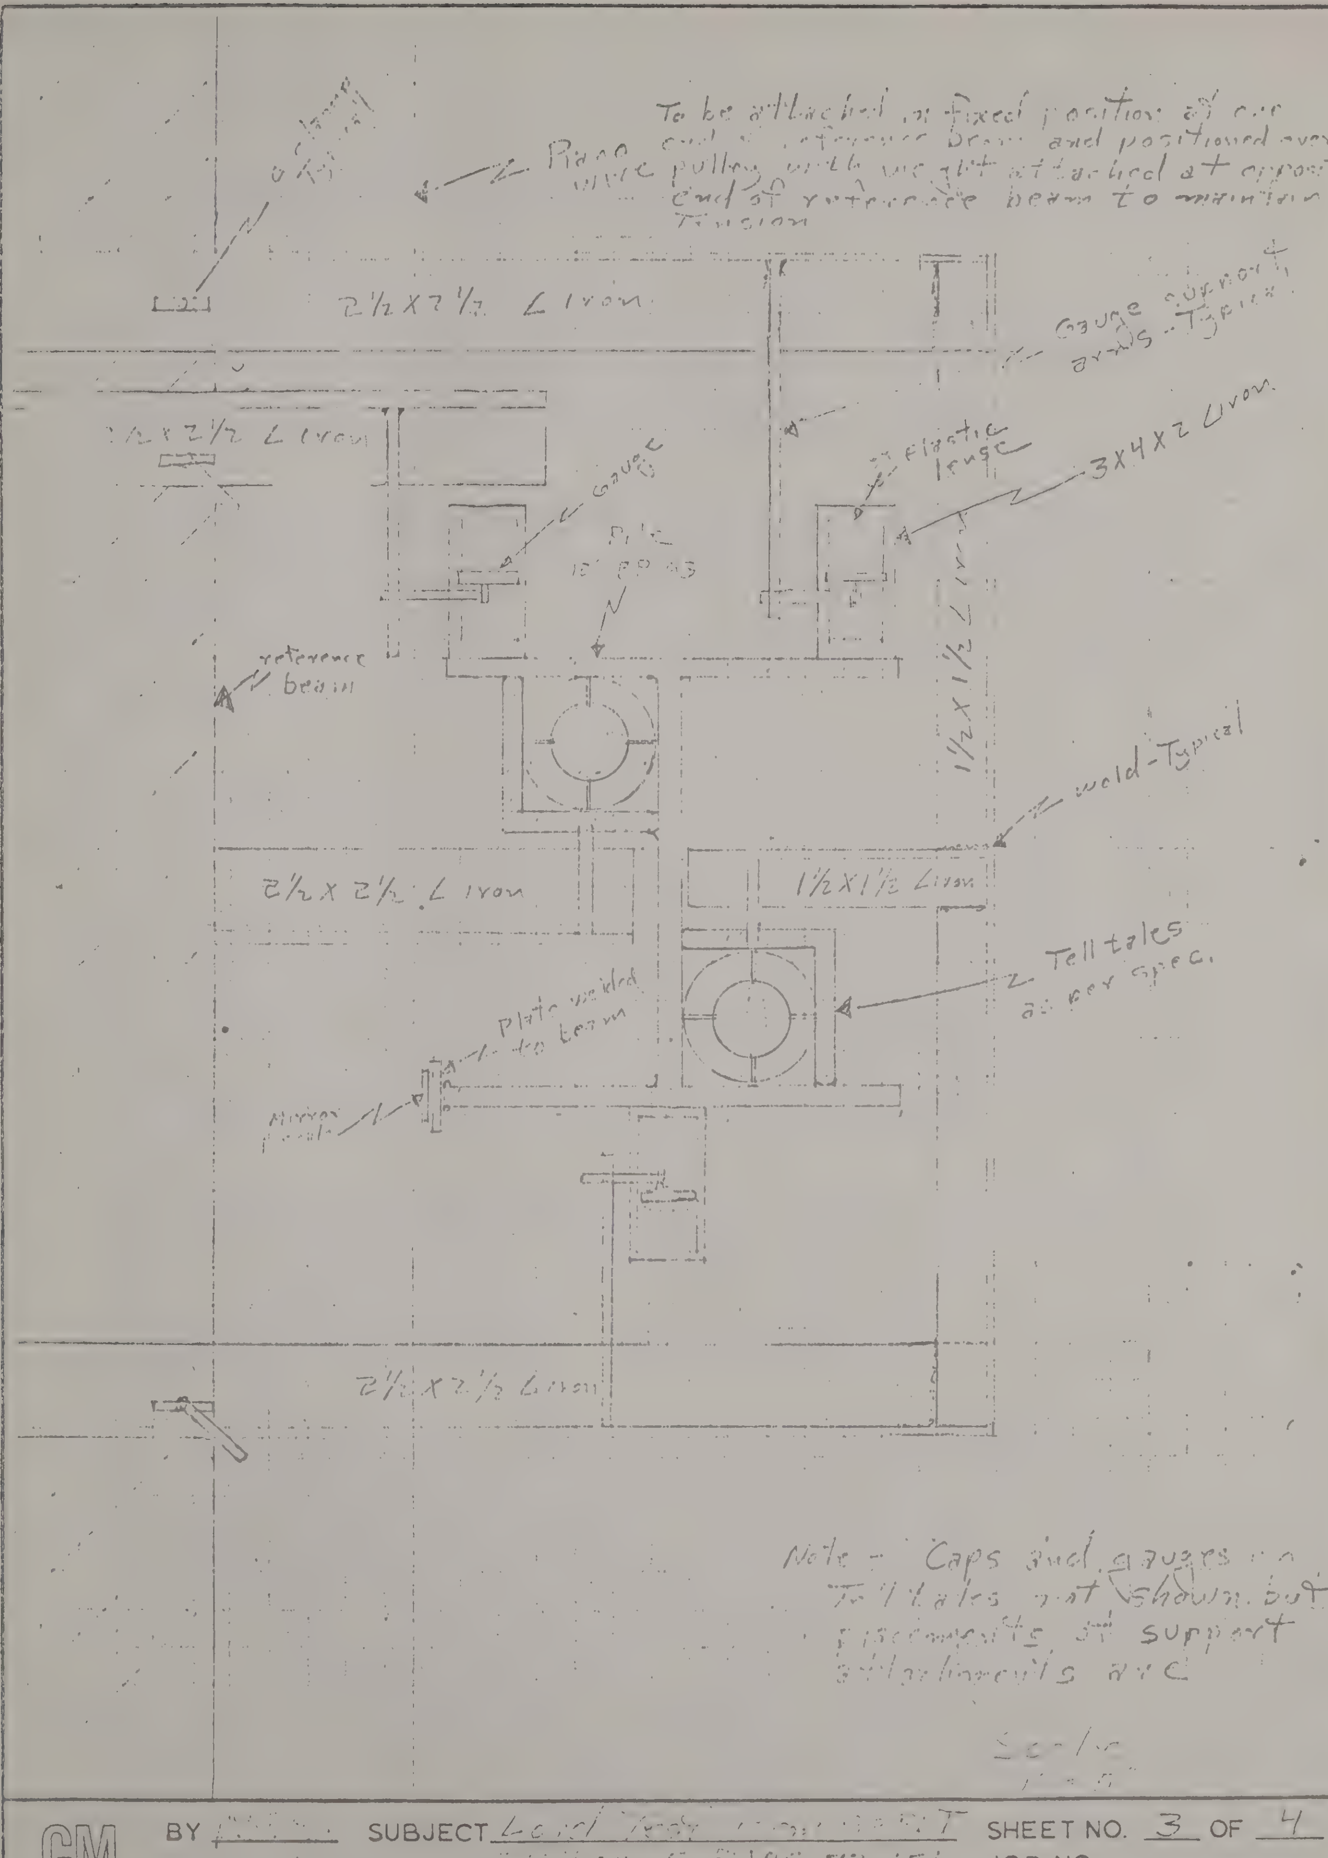
DATE _____ JOB NO. _____



GM BY [illegible] SUBJECT Load Test [illegible] SHEET NO. 3 OF 4

DATE 5/[illegible]/72 [illegible] JOB NO. ______

1. All details and dimensions not shown will conform to the requirements of the specifications as delineated in section Item 88 PLT-Pile Load Test.

2. The hydraulic jack pressures will be regulated automatically by a nitrogen compensation unit as shown in enclosed literature.

3. Because of space requirements for the amount of devices used it was deemed impractical to install the reference beam at the same elevation as the top of the pile. It is located approximately 6" below Top of Pile elevation.

4. We propose to use the dial adjacent to the webb as the governing dial in the C.R.P. Test. We are developing a pacer unit to control the C.R.P. rates to eliminate error in time and pumping pressures to achieve rate of penetration. The jack pressures will be controlled by a valve which eliminates the possibility of not being able to pump fast enough by hand to achieve rate of penetration.

5. The firm of Raamot Associates will be the engineers on the test. They are well experienced in all phases of Pile Load Testing. Raamot's Syracuse office will be handling the test.

6. Tell Tales are placed on opposite sides of webb to maintain a symmetrical configuration which will reduce the effects of the Tell Tales on the driving characteristics of the pile.

GENERAL NOTES

The subsurface explorations shown hereon were made between November 14, 1970 and December 17, 1971 by the Regional Soils Section.

1) General Soil Strata descriptions and indicated boundaries are based on interpretation of all available subsurface information and may not necessarily show the actual variation in subsurface conditions between borings and samples.

2) The observed water levels and/or conditions indicated on the soil profiles are as recorded at the time of drilling. These water levels and/or conditions may vary considerably, with time, according to the prevailing climate, rainfall and other factors.

3) Sound engineering judgment was exercised in preparing the subsurface information presented hereon. This information was prepared and is intended for State design purposes only. Its presentation on the plans or elsewhere is for the purpose of providing others with access to the identical information available to the State. This information is presented in good faith but is not intended as a substitute for personal investigation, interpretations or judgment of the Contractor.

4) All structure details shown hereon are for illustrative purposes only and may not be indicative of the final design conditions shown in the contract plans.

LEGEND

The following tables summarize the descriptive information used on this profile.

DH Drill Hole

Amount of Component Material	
Primary Component Capitalized	
"and"	30% to 40% of secondary component
"some"	40% to 10% " " "
"trace"	10% to less " " "

Density (Non Plastic Soils)	Avg. No. of Blows per foot for 18 in. drop of 300 lb. hammer 2 in. O.D. Sampler
Very Loose	0-3
Loose	3-8
Medium Compact	8-20
Compact	20-35
Very Compact	over 35
Consistency (Plastic Soils)	
Very Soft	0-2
Soft	2-4
Firm	4-12
Stiff	12-20
Hard	over 20

*Laboratory grain size distribution test summary notes:

1. The soil samples used for these tests were extracted with a 1⅜" nominal inside diameter sample spoon.
2. The test method used for these grain size analyses conforms to ASTM Designation D422 as modified by Bureau of Soil Mechanics Technical Manual No. TM(s) 64-2.
3. It was necessary to combine samples of similar visual description to obtain sufficient material for the grain size tests.
